## An image

Definition

A picture is a 2D matrix, each cell contains a number (resp. a triplet of numbers) corresponding to the gray level (resp. the color). Each cell is called a pixel (picture element).

http://images.math.cnrs.fr

source :

9/112

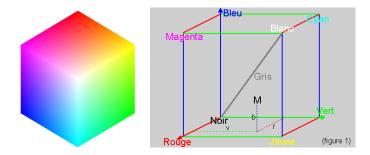

Pixels in grayscale images represent a level of intensity. Pixel values range from 0 (black) through all shades of gray to 255 (white).

### An image Color pixels

Color pixels are triplets of numbers representing the intensities of Red, Green and Blue (R,G,B).

José Mennesson (IMT N	IE)

→ ∃ →

## An image openCV Library

 $\mathsf{OpenCV}$  (Open Source Computer Vision Library) is an open-source library which allows to do :

- computer vision;
- machine learning.

Applications are :

- detect and recognize faces;
- recognize objects;
- classify human actions in videos;
- tracking moving objects;
- recognize scenes for augmented reality, etc.

Over 47000 users and over 18 million downloads.

Interfaces C++, Python, Java and MATLAB and can be installed on Windows, Linux, Android and Mac OS.

## An image Demo openCV/Python

- Open a picture file;
- display an image;
- display pixels;
- get a pixel;
- change of pixel value.

э

< (T) >

## Image processing

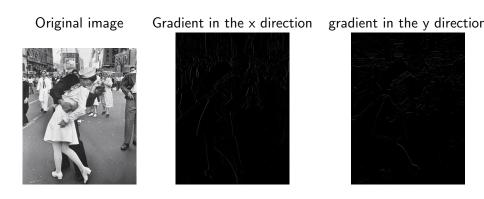

Images are matrices. You can then perform operations on these images, such as addition, subtraction, division...

## Image processing

Image gradients

The x-derivatives (on the columns) and y-derivatives (on the rows) of the image are called image gradients. This gives us the image's vertical and horizontal contours.

## Histogram of an image Definition

The histogram of an image is a graphical representation of the distribution of pixel values in the image.

source : https://avecunphotographe.fr

JOSE MIEITIESSON (INTI INL)	José Mennesson (	(IMT NE)	
-----------------------------	------------------	----------	--

A D N A B N A B N A B N

Histogram computation

We count the number of pixels for each intensity between 0 and 255. For example, considering the image :

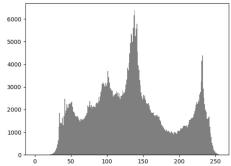

5	2	3	6
4	2	4	7
1	4	6	7
5	2	4	6

The associated histogram is :

Intensity	0	1	2	3	4	5	6	7	 255
Number of pixels	0	1	3	1	4	2	3	2	 0

Histogram of a natural image

### Histogram of an image Color thresholding

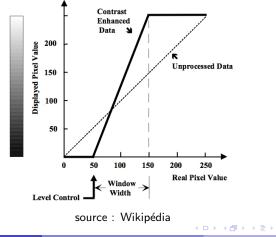

It's the same ! But we're going to threshold the three color channels (R,G,B). This can be used to extract an object from the scene.

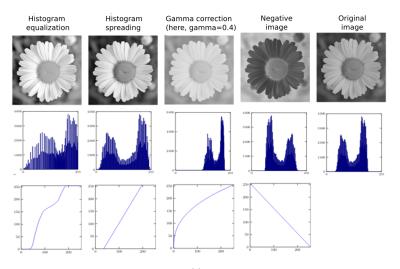

22/112

#### The Lookup Table (LUT)

A LUT is a mapping table between an original pixel intensity and a desired pixel intensity. By varying this mapping table, we can influence image intensity.

#### Intensity transformations

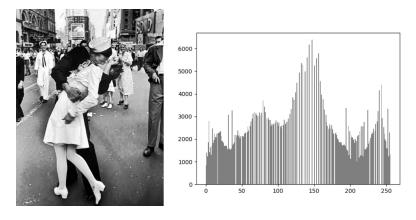

source : http://miv.u-strasbg.fr

э

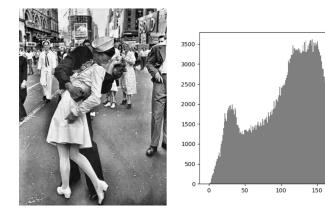

Histogram equalization [Gonzalez, Woods, and Eddins 2004]

The aim is to spread the histogram so that grayscale takes up the entire grayscale range between 0 and 255. This results in an overall improvement in image contrast.

Contrast Limited Adaptive Histogram Equalization (CLAHE) [Pizer et al. 1987]

In this method, the aim is to increase contrast locally (in areas of size  $8 \times 8$ ). In these areas, the histogram is equalized in the conventional way.

# Image analysis: a need for semantics What's in the picture?

## Detection/segmentation/recognition

José

- **Image segmentation** is the action of partitioning the image into several zones according to pre-defined criteria.
- **Object detection** is the operation of searching for the position of a specific type of object in the image. The result is often in the form of bounding boxes.
- **Object recognition** is the action of determining the class (car, person, building, etc.) of an object in the image.
- **Semantic segmentation** is the fusion of segmentation and object recognition.

Image thresholding

Very simple to implement but... very sensitive and not very selective!

Otsu's method [Otsu 1979] allows to automatically threshold grayscale images without setting a prior threshold.

K-means algorithm [MacQueen et al. 1967; Tou and Gonzalez 1974]

The idea is to divide pixel colors into K color classes. The algorithm will then automatically partition the pixel colors into K groups. In the example below, we took K=4.

K-means algorithm

- Initialization: partition objects by any method (random partition for example)
- **2** Step 1: for each class, calculate the centroid.
- Step 2: assign each object to the nearest centroid. If at least one object has changed class, return to step 1 else: END

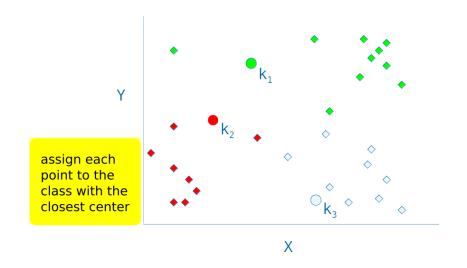

In the case of color image segmentation, each object is a pixel of the image.

K-means algorithm

José Mennesson (IMT NE)

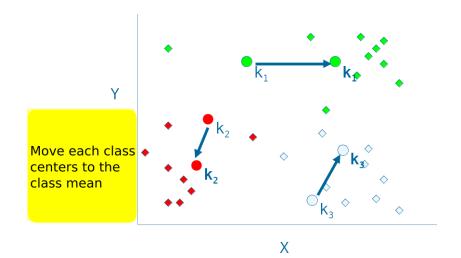

K-means algorithm

#### K-means algorithm

#### K-means algorithm

#### K-means algorithm

æ

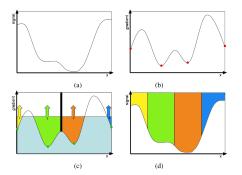

A D N A B N A B N A B N

Properties of the K-means algorithm

- The advantage of this method is that it converges quickly to a local optimum.
- On the other hand, the local optimum encountered is highly dependent on the initial choice of class centers, so this is not necessarily a good solution.
- In general, in order to improve the solution, you need to try out several initial conditions.
- K-means, as described earlier, works quite well if the number of classes required is moderate.
- As the number of classes increases, the solution found by the algorithm is mediocre, or even very bad (2 or 3 times less good than the optimal solution).

#### The watershed method

We consider a grayscale image as a topographic relief, and we simulate flooding. One-dimensional illustration of Watershed.

(a) the signal to be segmented.
 (b) The corresponding signal gradient.
 (c) Gray-scale flooding around each local minimum. When two different floods meet, a dam is built.
 (d) The resulting signal segmentation.

source : [Roudier et al. 2008]

Interactive segmentation : color watershed [Meyer 1992]

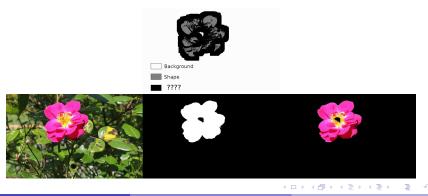

In practice, we need to annotate "seeds" on the objects we want to segment. These seeds can be defined automatically by pre-processing.

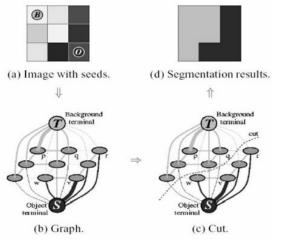

50 / 112

Interactive segmentation : the Grab-cut [Rother, Kolmogorov, and Blake 2004]

- User annotates objects to be segmented
- The algorithm estimates the color distribution of the target object and the background using a Gaussian mixture model.
- S An optimization based on graph cutting (GraphCut) is performed.
- This two-step procedure is repeated until convergence is reached.

< □ > < 同 >

Once the image has been partitioned into several "consistent" areas, how can we tell which objects are contained in these areas?

Objects must be characterized by extracting invariant (to illumination, geometric transformations, occlusions, etc.) features. In other words, features calculated for an object do not vary (or vary only slightly) if its appearance in the image changes.

We call these features image or shape descriptors !

### Feature extraction : descriptors

Originally, descriptors were defined "Handmade" by making assumptions about the type of object to be recognized.

For example, if we want to recognize a type of flower, we will extract the following descriptors:

- the mean color
- the number of petals
- the number of sepals
- the stem length
- etc.

Two types of descriptors can be calculated:

- Global descriptors (computed over the entire object or image)
- Local descriptors (computed near points of interest)

To be relevant, descriptors must have minimum intra-class variance and maximum inter-class variance!

#### Feature extraction : descriptors Global descriptors

Here is a list of global descriptors from the literature:

- Color histograms [Van De Sande, Gevers, and Snoek 2009]
- Texture histograms [Manjunath et al. 2001]
- Hue and Zernike moments [Khotanzad and Hong 1990; Liao and Pawlak 1996]
- Fourier descriptors [Smach et al. 2008]
- Local Binary Patterns (LBP) [Ahonen, Hadid, and Pietikäinen 2004]

etc.

Please note! This only works if the object to be recognized has been segmented beforehand!

57 / 112

## Feature extraction : descriptors

Local descriptors are features computed near points of interest. This method has several advantages! One can recognize an object when

- the background is not uniform;
- the object of interest cannot be easily segmented;
- the image contains several objects;
- there are wide variations in the object's point of view (3D rotation, affine transformations, etc.).

## Feature extraction : descriptors

Extraction of points of interest

Points of interest are points in the image that respect some properties:

- It has a clear definition, preferably mathematically based;
- It has a well-defined position in image space;
- The local structure of the image around the point of interest is rich in local information content;
- It is stable under local and global disturbances in the image domain like illumination/brightness variations, so that points of interest can be reliably calculated with a high degree of repeatability.

59/112

We can extract points of interest of several types:

- The Moravec detector[Moravec 1980]
- The Harris detector [Harris, Stephens, et al. 1988]
- The DoG (Difference of Gaussians) [Lowe 2004], the LoG (Laplacian of Gaussian) [Lindeberg 1998] or the DoH (Determinant of Hessians) [Lindeberg 1998].

The Harris detector [Harris, Stephens, et al. 1988]

< 1 k

- ∢ ⊒ →

#### The Harris detector [Harris, Stephens, et al. 1988]

The Harris detector [Harris, Stephens, et al. 1988]

The points are invariant to:

- 2D rotations;
- Lighting changes;
- Orientation of the object;
- Point of view.

But no invariance when changing scale !!!

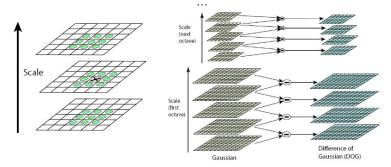

Up close, it's a contour...

From a distance, it becomes a corner!

63/112

DoG detector [Lowe 2004]

Scale invariance is obtained with DoG !

source : [Lowe 2004]

64 / 112

A D N A B N A B N A B N

Some local descriptors of the State of the Art :

- the SIFTs [Lowe 2004]
- the SURFs [Bay et al. 2008]
- the ORBs [Rublee et al. 2011]
- compute global descriptors in the neighborhood of points of interest (Fourier, Moments, LBP, etc.)

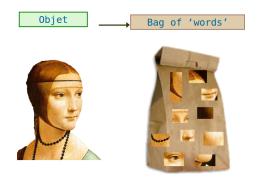

## Local descriptors

SIFT descriptors[Lowe 2004]

- Get the scale (by DoG maximization in scale and space)
- Determine local focus (dominant gradient direction)
- Compute the histogram
- Divide the patch into 4x4 sub-patches
- Compute the histogram of gradient orientations (on 8 reference angles) within each sub-patch 16 windows, i.e. 128 values for each point (4x4 histograms of 8 bins)
- Normalize descriptor to be invariant to intensity change

A representation of the image: the BAG OF WORDS [Sivic and Zisserman 2008]

→ ∃ →

67 / 112

A representation of the image: the BAG OF WORDS [Sivic and Zisserman 2008] Method

First, take a set of images,

- extract visual features;
- build a "dictionary" or "visual vocabulary"  $\rightarrow$  a list of common features.

Given a new image,

- extract features;
- for each feature, build a histogram;
- find the nearest visual word in the dictionary.

68 / 112

# A representation of the image: the BAG OF WORDS [Sivic and Zisserman 2008]

# From descriptors to object recognition

#### First solution $\rightarrow$ Image matching :

On dataset images :

- Detect points of interest;
- Compute visual features around these points;
- Export features in a usable format.

For a test image :

- Detect points of interest;
- Compute visual features around these points;
- Computes matches between these features and those in the database
- Find the corresponding image(s) and rank them their similarity score (from closest to farthest).

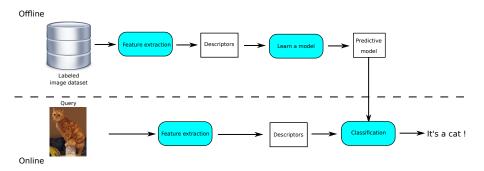

From descriptors to object recognition

#### Second solution $\rightarrow$ Machine learning

- Learn a model from a learning dataset
- Ø Matching the features of the test image to the model

Machine learning, artificial learning or statistical learning is a field of study in artificial intelligence that relies on mathematical and statistical approaches to give computers the ability to learn from data, i.e. to improve their performance in solving tasks without being explicitly programmed for each one. More broadly, it concerns the design, analysis, optimization, development and implementation of such methods.

#### Supervised learning

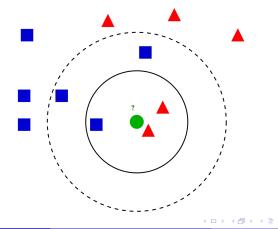

A D N A B N A B N A B N

79/112

э

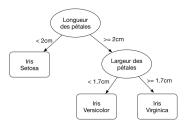

#### The KNN (K - nearest neighbors ) [Fix 1951]

The method is simple: we compute the distance between the descriptors of the query and the descriptors in the database. Then, we consider the classes of the K-closest observations. The most represented class will be chosen.

**Decision Trees** 

- One of the input variables is selected at each internal node of the tree.
- Each edge to a child node corresponds to a set of values of an input variable.
- Each leaf represents either a value of the target variable, or a probability distribution of the various possible values of the target variable.
- The combination of input variable values is represented by the path from the root to the leaf.

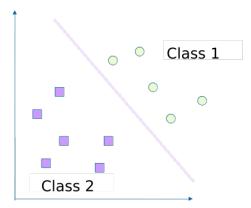

For exemple, one can use Random Forest [Breiman 2001].

A B b A B b

Support vector machine : SVM [Duda, Hart, et al. 2006]

- Dealing with non-linear discrimination problems, and reformulating the classification problem as a quadratic optimization problem
- Notion of maximum margin :
  - the distance between the separation boundary and the nearest support vector samples must be as great as possible.
- The input data are embedded in a higher-dimensional space in which a linear separator is likely to exist.
  - Kernel functions !

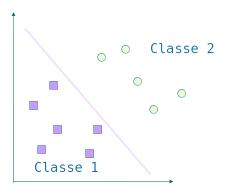

Linearly separable two-class problem

 Several decision surfaces exist to separate the classes

Which one to choose?

### Machine learning Example of a bad choices

э

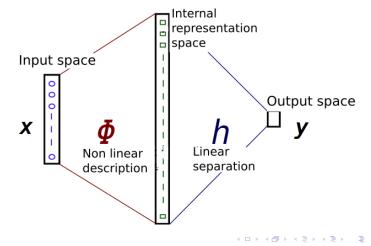

#### Hyperplane with wider margin

		ㅁ › 《圖 › 《필 › 《필 ›	E Sac
José Mennesson (IMT NE)	UV LARM	December 29, 2024	85 / 112

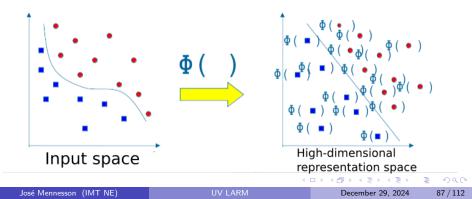

Extension to a non-linear separation surface

• Idea ! simplify things by transforming X into a higher-dimensional space

Extension to a non-linear separation surface

- Potential problems with the transformation
  - High computation effort and difficulty in obtaining a good estimate
- SVM with kernel functions solves both problems
  - Using kernel functions for computational efficiency

The kernel trick

- Find φ( ) is very hard !
- Definition of a kernel function :

$$K(x,y) = \langle \phi(x), \phi(y) \rangle$$

- K(x,y) intuitively represents the similarity between x and y, obtained from our a priori knowledge
- However, K(x,y) must satisfy certain conditions for the corresponding  $\varphi(\ )$  to exist.

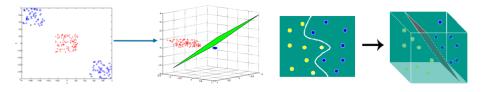

The kernel trick

José M

#### Solving a non-linear case We change dimension using a kernel function

- Linear K(x,y) = x \* y
- Polynomial  $K(x,y) = (x * y + \theta)^d$
- Gaussian  $K(x,y) = exp(-\alpha ||x-y||^2)$
- **Perceptron**  $K(x,y) = -||x y||_2$

#### The new space is called "description space".

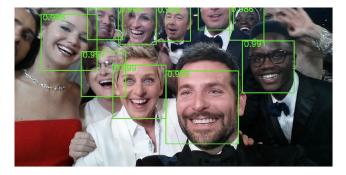

1ennesson (IMT NE)	UV LARM	December 29, 2024	89/112

A D N A B N A B N A B N

# Object detection

Object detection involves estimating the position (often a bounding box) of some type of object in an image. One or more objects can be detected in the same image.

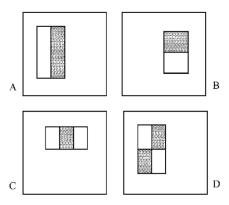

Face detection is now a common feature of digital cameras and cell phones.

< □ > < □ > < □ > < □ > < □ > < □ >

# **Object detection**

#### Viola and Jones algorithm[Viola, Jones, et al. 2001]

The method is to exhaustively search within the image for image parts containing the desired object. This exhaustive search can be very time-consuming. To make this search as quick as possible, features that can be computed quickly have been proposed (pseudo-Haar features).

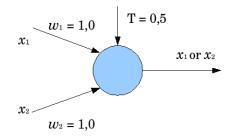

For learning, Viola-Jones uses a variant of Adaboost classifier.

The principle comes from the combination of weak classifiers (also called hypotheses). By successive iterations, the knowledge of a weak classifier is added to the final classifier (strong classifier).

Originally dedicated to face detection, the Viola-Jones algorithm can be trained using the openCV library to detect any object. See https://docs.opencv.org/2.4/doc/user\_guide/ug\_traincascade.html

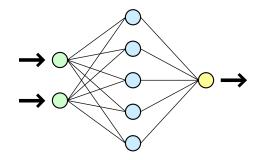

What is a neuron?

A formal neuron is a mathematical and computational representation of a biological neuron. In its simplest version, a formal neuron calculates the weighted sum of the inputs received, then applies an activation function, generally non-linear, to this value. The final value obtained is the output of the neuron.

What is a neural network ?

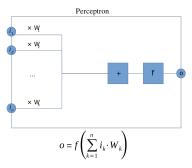

A neural network is a computer system that enables learning to be carried out by the cooperation of a set of neurons structured in layers. Data is passed to the input layer of the neural network. At the output of the network, one or more outputs are retrieved.

Learning corresponds to calculating the weights of each input connected to the neuron.

#### The perceptron [Rosenblatt 1958]

This is the simplest type of neural network. It enables linear classification. Descriptors can be given as input and, as output, we can have one or more outputs corresponding to each of the classes considered.

For multi-layer perceptrons, weights can be learned using a backpropagation algorithm. [Kröse et al. 1993].

Deep-Learning

Nowadays, most computer vision processing is carried out using deep neural networks (Deep Learning). These are neural networks containing many layers of neurons.

In computer vision, one type of neural network is used in particular for its properties:  $\rightarrow$  convolutional neural networks.

Convolutional neural networks [LeCun et al. 1998]

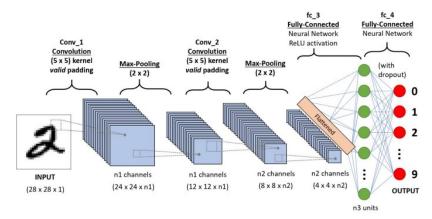

The aim of convolutional neural networks is to learn how to extract the most discriminating features from images in order to carry out a task, unlike previous "handcrafted" approaches.

To do this, they perform convolutions on the images to extract discriminating features. To extract features at different "scales", pooling (reducing the image size) is performed between each convolution.

At initialization, the convolution filters are set at random. During training, they evolve according to the database and the task to be performed.

#### Convolutional neural networks [LeCun et al. 1998]

Example of a convolutional neural network for recognizing handwritten digits.

Networks are becoming increasingly complex...

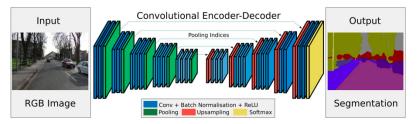

One of the most widely used networks is called an auto-encoder. It consists of a convolutional network (encoder) followed by a so-called "deconvolution" network (decoder).

The encoder compresses the signal to obtain only the most important information.

The decoder allows to return to the original configuration (an image with the same dimensions as the original).

... for increasingly complex tasks

Example of a encoding-decoding neural network for semantic image segmentation. Semantic segmentation corresponds to image segmentation and recognition of segmented objects at the same time. Each pixel in the image is assigned a class.
